Abstract: It is difficult to make diagnosis and treatment decision for patient with bilateral multiple pulmonary foci. Surgical resection can offer sufficient specimens for diagnostic differentiation and the greatest chance for long-term survival in patient with presumptive synchronous multiple primary lung cancers (SMPLC). Since uniportal video-assisted thoracoscopic surgery (VATS) is a less invasive technique and has been attempted in lung cancer surgery, we transferred it into the management of SMPLC. In this paper, we report two cases of bilateral SMPLC managed through single-staged uniportal VATS with major pulmonary resection. This successful attempt provides an optimized idea to accomplish simplified mini-invasive diagnosis and synchronous treatment using the less invasive uniportal VATS technique for the management of SMPLC, especially for those with multiple bilateral lesions.

Introduction

Difficulty in diagnosis and treatment decision making for patient with bilateral multiple pulmonary foci usually raises a clinical dilemma for clinicians. An aggressive surgical approach can offer sufficient specimens for diagnostic differentiation and the greatest chance for long-term survival in patient with presumptive synchronous multiple primary lung cancers (SMPLC) (1,2). In such situation, mini-invasive technique of video-assisted thoracoscopic surgery (VATS) has been reported to be effective (1,3,4). Since uniportal VATS has been attempted as a less invasive technique (5), we transferred it into the management of presumptive SMPLC. Here, we present two cases of bilateral SMPLC managed through single-staged uniportal VATS with major pulmonary resection, which provides simplified mini-invasive diagnosis and synchronous treatment.

Cases report

Patient 1 was a 67-year-old female, who was presented with chest pain for about 2 months. Preoperative high-resolution computed tomography revealed four ground glass opacity (GGO) lesions (two in the right upper lobe, each in the left upper and lower lobe, respectively, Figure 1A-D). Patient 2 was a 53-year-old female, who was admitted with a mass in the right upper lobe (Figure 1E) and a GGO lesion in the superior segment of the left lower lobe (Figure 1F). Both of them were presumptively diagnosed with bilateral SMPLC. The preoperative staging work-up indicated no sign of lymphadenopathy or distal metastasis. Given no surgical contraindication, single-staged uniportal VATS for bilateral pulmonary foci was planned for each of them with written informed consent.

General anesthesia with double-lumen endotracheal intubation was administered to each of them. A 5 mm 30° thoracoscope was used for inspection. Patient 1 was firstly placed in a right lateral decubitus position. On the left, a 3.5 cm incision was made in the fourth intercostal space at the anterior axillary line. Each of the two lesions was identified through digital palpation and the surface of the lung right on the top of each lesion was marked.
using a suture, which was also used for retraction during resection. Then wedge resections were performed using curved endostaplers with margins ≥2 cm. Frozen-section examination confirmed an adenocarcinoma in the upper lobe and a carcinoma in situ in the lower lobe. One chest tube was placed at the posterior part of the incision. After the left-side operation, the patient was rotated to the opposite side for right upper lobectomy. Cushions were used to lift the patient to avoid kicking or compression to the contralateral chest tube during positioning. On the right, a 4.5 cm incision was made in the fifth intercostal space at the anterior axillary line (Figure 1G). Right upper lobectomy (Figure 2) was performed with the right upper pulmonary vein, arterial branches, bronchus and pulmonary fissures dissected and divided sequentially. Then frozen-section examination confirmed two adenocarcinomas and systematic lymph node (LN) dissection was performed (a total of 7 stations and 15 LNs were harvested). One chest tube was placed at the posterior part of the incision. Patient 2 was also firstly placed in a right lateral decubitus position to undergo left lower lobe superior segmentectomy (Figure 3) via a 4.5 cm incision made in the fifth intercostal space at the anterior axillary line. The superior segmental artery, bronchus, drainage vein, and the intersegmental plane were dissected and divided sequentially. Frozen-section examination confirmed an adenocarcinoma followed by

Figure 1 (A-D) High-resolution computed tomography (HRCT) reveals four ground glass opacity (GGO) lesions of patient 1 (a 3.2×1.5 cm lesion located at the apical segment of the right upper lobe, a 1.3×1.0 cm lesion located at the posterior segment of the right upper lobe, a 1.0×0.8 cm lesion located at the apical segment of the left upper lobe, and a 0.8×0.8 cm lesion located at the posterior basal segment of the left lower lobe); (E,F) HRCT reveals two tumor-like lesions of patient 2 (a 3.0×2.5 cm mass located at the posterior segment of the right upper lobe and a 1.6×0.9 cm GGO lesion located at the superior segment of the left lower lobe); (G) surgical image of instrumentation during right upper lobectomy.
systemic LN dissection (a total of four stations and seven LNs were harvested). After the left-side procedure, she was rotated to the opposite side for right upper lobectomy followed by systemic LN dissection (a total of five stations and seven LNs were harvested) after confirmation of adenocarcinoma by frozen-section examination. Chest tube strategy was the same as did for patient 1. The operation time for patient 1 and 2 were 260 and 285 min, respectively. The intraoperative blood loss of patient 1 and 2 were 30 and 60 mL, respectively. The postoperative courses were both uneventful. Pathological examination documented four primary lung cancers of patient 1 (right upper lobe, two minimally invasive adenocarcinomas, T2aN0M0 and T1aN0M0, respectively; left upper lobe, minimally invasive adenocarcinoma, T1aN0M0; left lower lobe, adenocarcinoma in situ, TisN0M0) and two primary lung cancers of patient 2 (right upper lobe, acinar predominant adenocarcinoma, T1bN0M0; left lower lobe, lepidic predominant adenocarcinoma, T1aN0M0).

Discussion

The common criteria used for differentiating between SMPLC and intrapulmonary metastases depend on the results of pathologic examination and even molecular and genomic analysis (8). However, preoperative diagnosis is often difficult due to difficulty in obtaining sufficient specimens for histological examination whether through bronchoscopy or percutaneous puncture, especially for those small peripheral lesions. Single-staged procedures executed via traditional multiportal VATS have been demonstrated to be feasible and safe for selected patients with bilateral SMPLC (3). Although it may be also reasonable to perform delayed resections for some small GGO lesions with no negative effect on outcomes (9), we
prefer to perform single-staged surgery when the lesions are highly suspected of malignancy. Since introduced by Rocco et al. in 2004 (10), sporadic reports on uniportal VATS for lung cancer have been published (5,11,12). Uniportal VATS causes less postoperative pain and fewer paresthesia owing to less intercostal space involved (13). For our patients, it's hard to procure thorough diagnoses for all lesions through neither bronchoscopy nor percutaneous puncture due to their disperse locations, small sizes, and manifestations of GGO. To simplify the diagnosis and treatment course, we transferred the less invasive technique of uniportal VATS into the management of SMPLC to achieve mini-invasive diagnosis and synchronous treatment. Systemic LN dissection is routinely performed when anatomic pulmonary resection (lobectomy or segmentectomy) is planned in our daily work. But for pure GGO lesions, especially those ≤1 cm, wide wedge resection with adequate free margin seems to be oncologically enough because there is seldom invasiveness or LN involvement (14). Therefore, we didn’t perform LN dissection for the left side of patient 1 while station seven would be dissected from the right side.

This successful attempt first demonstrates the feasibility of simplified mini-invasive diagnosis and synchronous treatment using bilateral uniportal VATS major pulmonary resection for the management of SMPLC with multiple bilateral lesions.
